GREPO

Grepo is a developer tool that helps users understand unfamiliar codebases by visualizing their structure, tracing source-linked relationships, and surfacing code worth investigating.

Why Grepo?

- **Source-linked insights:** Every finding points back to the files and lines that support it.
- **Transparent analysis:** Unresolved relationships are clearly identified as limitations rather than presented as facts.
- **Built for verification:** Developers can inspect the underlying code and validate findings in the same workspace.

- Finding the right files and functions takes time.
- Dependencies and change impact are hard to trace.
- Documentation may be incomplete or out of date.
- Existing reusable code can be easy to miss.

Problems

Large codebases can be difficult to navigate, especially when you're new to a project.

Before making a change, developers often have to first figure out where the relevant code is and how it connects with other files.

Solution

Grepo turns a ZIP or public GitHub repository into an interactive workspace.

Explore the project structure, inspect source-linked summaries and relationships, and review potential reuse, duplicate, and unused-code findings.

Features

- **Project Structure:** Searchable file tree and interactive architecture map.
- **Generate Summaries:** Source-cited summaries you can verify against the code.
- **Dependencies:** Explore discovered relationships and understand the potential impact of code changes.

Features

- **Reusable Functions:** Find functions that appear to be called across files.
- **Duplicate and Unused Functions:** Find functions that are potentially useless.
- **Codebase AI Chat:** Ask questions about the repository with optional AI chat feature.

How it works

Codebase

Safe import into a snapshot

Static analysis

Source-linked graph and findings

Grepo workspace

System Architecture

React + TypeScript frontend

FastAPI backend

Import and snapshot services

Python AST/Tree-sitter analysis

Snapshot data, evidence, and graph

Interactive map rendered with Archify

System Architecture

- **Frontend:** React and TypeScript provide the searchable tree, map, source viewer, and analysis panels.
- **Backend:** FastAPI handles repository imports, snapshot access, analysis requests, and source retrieval.
- **Analysis:** Python files use Python's AST; Tree-sitter extracts syntax facts across additional languages. Dependency resolution is implemented for Python and JavaScript/TypeScript.

System Architecture

- **Visualization:** The backend prepares a structural map artifact; Archify renders it in the browser.
- **Feature integration:** Analysis panels use typed frontend feature registrations and versioned API endpoints.

Evidence and Safety

- Imports become immutable, snapshot-scoped workspaces.
- Analysis reads extracted syntax and source; it does not execute imported repository code.
- Findings link to canonical file IDs and line ranges.
- Evidence checks confirm the file belongs to the snapshot, the cited range is valid, and the source hash matches.
- Unresolved or ambiguous relationships are reported as limitations instead of being drawn as certain connections.
- Parsing and responses have resource and size bounds.

- **Summaries:** validated the cited-summary approach, then implemented a deterministic summaries engine with evidence verification.
- **Dependencies:** built dependency analysis and change-impact behavior, then added guards for defects found through testing.
- **AI Chatbot:** wired the Ask feature into the interface and fixed response-rendering issues.
- **Workspace:** supported the initial structure workspace implementation and repository setup.

IBM BOB

Development Workflow

We used IBM Bob throughout development to investigate, implement, test, and refine Grepo features.

- 39.88 Bobcoins recorded across the listed task panels.
- 17.95 for cited-summary analysis and the summaries engine.
- 8.10 for dependency analysis and change impact.
- 7.13 for the impact correction, dependency target guard, and Ask rendering fix.
- 4.80 for Ask slot wiring and greeting.
- Context usage across those panels ranged from 13% to 41% of the 270k budget.

IBM BOB

Session Evidence

Bob session evidence is organized in numbered task folders under bob_sessions. Each folder preserves the task's original ID and available summary, transcript, and screenshots.

Impact

Grepo aims to help developers:

- Clearly navigate through unfamiliar codebases faster.
- Trace relationships before changing code.
- Find existing code that may be reusable

Future

Grepo aims to improve and add on:

- Broader language support
- Deeper semantic analysis
- Stronger summaries and Q&A

THANK YOU
